Sticking Probability of H_2 and HD on Noble Metal Surfaces

M. D. Stiles and J. W. Wilkins

Laboratory of Atomic and Solid State Physics
Cornell University
Ithaca, NY 14853

One-phonon distorted-wave Born approximation calculations of the energy-dependent phonon-assisted sticking coefficients of H_2 and HD at smooth metal surfaces yield peaks in the sticking coefficient as a function of energy due to selective adsorption resonances, the peaks being strong for HD and weak for H_2. Furthermore the calculation does not explain the observed[1] dependence of the sticking coefficient of H_2 on the rotational populations.
